# 1.0 Introduction & Background

LandTech Consulting Ltd (LandTech) were engaged by Ngai Tahu Property to carry out lot specific shallow soil testing at Lot 13, 115 Eureka Street, Aranui (the site). The purpose of the shallow soil testing is to confirm subsurface conditions and provide geotechnical recommendations with regards to future residential foundations within the site.

We previously investigated the underlying larger property, which this lot has been formed from, to support the corresponding Resource Consent for the subdivision. Our findings are presented in a report titled: *Geotechnical Investigation Report for Proposed Residential Subdivision 115 Eureka Street, Aranui*, project reference: LTC21220, Revision B, dated 13 September 2021.

LandTech has been retained to monitor earthworks and ground remediation for the subdivision site. As earthworks are ongoing across the wider subdivision site at the time of preparing this letter, we have yet to prepare an Earthworks Completion Report for the subdivision. However, earthworks were mostly completed at this particular lot, with the exception of potentially some additional minor topsoil spreading, prior to our current shallow soil testing and had been carried out to the appropriate engineering standards. This report is considered relevant for the ground conditions beneath the lot at the time of testing, and any additional earthworks (ie topsoil spreading) will need to be taken into account for excavation depths of future house foundations. Depths of foundation excavations presented later within this report may therefore need to be increased at the time of house construction should additional topsoil be placed after the date of our testing.

## 2.0 Shallow Soil Testing

LandTech investigated the site on 24 May 2023, conducting two hand augers with corresponding Scala Penetrometer tests (SPs) and two additional SPs. The locations of the hand auger and SPs were measured using inferred lot boundaries and are approximate only. The test locations are shown on our LandTech *Test Location Plan*, Drawing No. Lot 13/ TLP, attached to this report.

Soil types and conditions within the hand augers were logged by LandTech technical staff in accordance with New Zealand Geotechnical Society *Guideline for the Description of Soil and Rock for Engineering Purposes* (2005). The hand auger logs for each hole are attached.

Our SP testing was carried out in accordance with NZS 4402:1988, Test 6.5.2, *Dynamic Cone Penetrometer*. The SP results are also attached.

Topsoil was encountered within the hand augers from the ground surface to 0.3m depth, which was typically a dark brown silty sand material with a trace of gravel. Engineered fill was encountered below the topsoil to the base of auger holes, which was a compacted brown sand material with a trace of silt. The hand augers were terminated at 1.2m depth below ground level to avoid damage to the geotextile layer which was installed at 1.5m depth below ground level. Groundwater was not encountered during testing.

As part of the subdivision earthworks, ground improvement consisting of a reinforced raft is being constructed across the site, which we observed the subgrade excavations for and monitored construction. The reinforced engineered fill raft comprises 250mm compacted sand layers, with a total thickness of 1200mm, capped with a minimum 300mm of topsoil. A layer of geotextile (AS410) was installed at the base of the engineered fill raft and three geogrid layers (Duragrid 40/40) were installed within it for reinforcement (at the base, 250mm, and 750mm).

SPs at each of the four locations returned results between 3 and 12 blows per 100mm penetration below the topsoil and within the engineered fill layer. SPs were terminated at 0.9m depth to confirm near surface bearing capacities, and to avoid damage to the geogrids and geotextile. In addition, the density of the engineered fill and bearing capacity of its underlying subgrade have been confirmed via extensive geotechnical inspection and fill compaction testing during subdivision earthworks.

#### 3.0 Foundation Recommendations

From our previous investigation in support of the subdivision, we concluded that TC2 foundations in accordance with MBIE Guidelines (December 2012) may be used at this site following subdivision earthworks and ground remediation (reinforced engineered fill raft). Our current lot-specific shallow soil testing confirms such foundations remain appropriate. In particular, we confirm Option 4 enhanced slab foundations are required.

All foundations must be embedded to a minimum depth of 0.3m below ground level, where an Ultimate Bearing Capacity of 200kPa and a strength reduction factor of (\$\phi\$s) 0.5 is available. Foundations excavations should expose engineered fill of appropriate bearing capacity. All topsoil and unsuitable materials should be removed below foundations and floor slab areas, and where required layers of compacted hardfill should be placed to the underside of foundations.

The ground improvement could not extend all the way up to the north-western boundary of the lot on account of temporary batters of approximately 1V:1H being formed down from the boundaries during construction to allow for the formation of the engineered fill raft. Therefore, a no-build setback to the greater of 2.0m, the depth of ground remediation, or the sum of the permanent cut face (existing ground level to finished ground level) plus the depth of ground remediation along these boundaries, shall be created along the corresponding boundaries. With reference to the Davie Lovell-Smith As-Built Earthworks Plans completed for the subdivision, the maximum depth of ground remediation was 1.4m, while the maximum permanent cut face is 0.4m high along some of the boundaries. Therefore, the 2.0m no-build setback governs along these boundaries to external neighbouring properties.

The external boundary of the lot to the north-eastern side is to the rear of a circa 0.6m tall retaining wall, which we understand has not been designed for surcharge loading from future housing within the lots. Should any building foundations, permanent earthworks, or additional retaining walls be constructed within 3.5 x wall height to the rear of the boundary retainer constructed during subdivision works, then these shall be subject to specific engineering design to make sure no undue surcharge is applied to the rear of the existing subdivision retaining wall.

#### 4.0 Limitations

This shallow soil testing report has been prepared for our client, Ngai Tahu Property, to support foundation design and corresponding Building Consent applications for future housing within the corresponding lot. This report shall not be extrapolated for other nearby sites or used for any other purposes without the express approval of LandTech and our client.

The findings of this report are based on the results of testing conducted at point locations and within the agreed scope of works. Therefore, while we have attempted to conduct a thorough investigation of soils across the site, local subsurface conditions could vary from those used in our geotechnical model, as soils can vary naturally and due to previous human activities. LandTech has no control over and should not be held accountable for these variations. Should exposed soil conditions vary from those described herein, we request to be informed so that we may assess the continued applicability of our recommendations.

Our geotechnical investigation described in this report was confined to geotechnical aspects of the site only and did not involve an assessment for environmental contaminants. Our investigation and analyses have not taken into account possible fault rupture that may cause deformations and displacements of the ground directly below the site. These assessments are outside the scope of our geotechnical engagement.

If you have any queries regarding this report, please contact the undersigned at your convenience.

Yours faithfully,

LandTech Consulting Limited
